Description

[0001] This invention generally relates to a catheter system which is suitable for intravascular procedures such as percutaneous transluminal coronary angioplasty (PTCA) and which allows for the exchange of guidewires and catheters during such procedures.

[0002] In classic PTCA procedures, a guiding catheter having a preshaped distal tip is percutaneously introduced into the cardiovascular system of a patient and advanced therein until the preshaped distal tip thereof is disposed within the aorta adjacent the ostium of the desired coronary artery. The guiding catheter is twisted or torqued from the proximal end to turn the distal tip of the guiding catheter so that it can be guided into the coronary ostium. A dilatation catheter having a balloon on the distal end thereof and a guidewire slidably disposed within an inner lumen of the dilatation catheter are introduced into and advanced through the guiding catheter to the distal tip thereof. The distal tip of the guidewire is usually manually shaped (*i.e.* curved) by the physician or one of the attendants before the guidewire is introduced into the guiding catheter along with the dilatation catheter. The guidewire is first advanced out the distal tip of the guiding catheter, which is seated in the ostium of the patient's coronary artery, into the patient's coronary artery. A torque is applied to the proximal end of the guidewire, which extends out of the patient, to guide the curved or otherwise shaped distal end of the guidewire as the guidewire is advanced within the coronary anatomy until the shaped distal end of the guidewire enters the desired artery. The advancement of the guidewire within the selected artery continues until it crosses the lesion to be dilated. The dilatation catheter is then advanced out of the distal tip of the guiding catheter, over the previously advanced guidewire, until the balloon on the distal extremity of the dilatation catheter is properly positioned across the lesion. Once properly positioned, the flexible, relatively inelastic balloon is inflated to a predetermined size with radiopaque liquid at relatively high pressures (*e.g.*, 4-12 atmospheres) to dilate the stenosed region of the diseased artery. The balloon is then deflated so that the dilatation catheter can be removed from the dilated stenosis and blood flow can then be resumed therethrough.

[0003] Further details of guiding catheters, dilatation catheters, guidewires, and the like for angioplasty procedures can be found in U.S. Patent 4,323,071 (Simpson-Robert); U.S. Patent 4,439,185 (Lundquist); U.S. Patent 4,468,224 (Enzmann *et al.*); U.S. Patent 4,516,972 (Samson); U.S. Patent 4,438,622 (Samson *et al.*); U.S. Patent 4,554,929 (Samson *et al.*); U.S. Patent 4,582,185 (Samson); U.S. Patent 4,616,652 (Simpson); U.S. Patent 4,638,805 (Powell); U.S. Patent 4,748,986 (Morrison *et al.*); U.S. Patent 4,898,577 (Badger *et al.*); and U.S. Patent 4,748,982 (Horzewski *et al.*).

[0004] Recently, the licensee of the present invention,

Advanced Cardiovascular Systems, Inc., introduced into the market place an improved dilatation catheter which is described in U.S. Patent 4,748,982 (Horzewski *et al.*) upon which the preamble of claim 1 is based. This dilatation catheter has a short guidewire-receiving sleeve or inner lumen extending through just the distal portion of the catheter. The sleeve extends proximally at least 10 cm, typically about 25 cm, from a guidewire port in the distal end of the catheter to another guidewire port in the wall of the catheter. A slit is provided in the catheter wall which extends distally from the second guidewire port to a location proximal to the proximal end of the inflatable balloon. The structure of the catheter allows for the rapid exchange of the catheter without the need for an exchange wire or adding a guidewire extension to the proximal end of the guidewire.

[0005] The catheter design embodying the Yock and Horzewski *et al.* improvements has been widely praised by members of the medical profession and has met with much commercial success in the market place. Nonetheless, there are some inconveniences in its use because the catheter does not allow for the exchange or replacement of the guidewire. For example, the shaped distal tip of the guidewire may become deformed in use or the shape of the distal tip or the size of the guidewire may be found to be no longer suitable for the particular procedure within the patient's vasculature. In this instance the physician might want to remove the guidewire and reshape the distal tip or replace the first guidewire with another having the desired size, stiffness or shape. However, when the guidewire in a dilatation catheter system embodying the Yock and Horzewski *et al.* improvements is removed, access to the desired arterial location through the distal guidewire lumen of the catheter is lost. Unfortunately, there is no way to clinically determine before the guidewire is inserted into the patient in an angioplasty procedure whether a guidewire or a catheter will have to be exchanged during the procedure.

[0006] What has been needed and heretofore unavailable is an intravascular catheter system which allows for the rapid exchange of either the catheter or the guidewire during an intravascular procedure without losing access to the desired region of the patient's arterial system. The present invention satisfies this and other needs.

SUMMARY OF THE INVENTION

[0007] Disclosed herein is an intravascular catheter system which is adapted for diagnostic or therapeutic procedures within a patient's vascular system and which allows the exchange of a guidewire or catheter thereof while the catheter system is disposed within the patient's vascular system or the catheter while the guidewire is disposed within the patient's vasculature, the system being characterized by: an elongated catheter body having proximal and distal ends and a

guidewire-receiving inner lumen therein extending to the distal end of the catheter body; means mounted on a distal portion of the catheter body for performing a diagnostic or therapeutic procedure within a patient's vasculature; a first guidewire port in the catheter body defining at least in part the guidewire-receiving inner lumen, the first port being at or near the proximal end of the catheter body and being in communication with the guidewire-receiving inner lumen; a second guidewire port in the wall of the catheter body defining at least in part the guidewire-receiving inner lumen, the second port being proximal to the means for performing the diagnostic or therapeutic procedures and being spaced at least 10 cm from the distal end of the catheter body and a substantial distance from the proximal end of the catheter body and being in communication with the guidewire-receiving inner lumen; a third guidewire port in the distal end of the catheter body in communication with the guidewire-receiving inner lumen; and a guidewire slidably disposed within the guidewire-receiving inner lumen.

[0008] This invention is directed to a catheter system which can be used in an over-the-wire type mode and which can also allow for the exchange of either a guidewire or a catheter mounted over a guidewire during an intraluminal procedure such as a PTCA without losing access to the body lumen and the method of using such a catheter system.

[0009] The catheter system of the invention generally comprises an elongated catheter body with proximal and distal ends, a diagnostic or therapeutic means, such as an inflatable balloon positioned on a distal portion of the body and a guidewire-receiving inner lumen extending within the body to the distal end thereof. The catheter body has a first guidewire port at or near the proximal end thereof, a second guidewire port in the catheter body between the first port and the diagnostic or therapeutic means, and a third guidewire port in the distal end of the catheter, all of which are in communication with the guidewire-receiving inner lumen within the catheter body. The first port is generally at or close to the proximal end of the catheter body, e.g. not more than about 30 cm therefrom, and, preferably, is not more than about 10 cm from the proximal end of the catheter body. The second port is spaced closer to the diagnostic or therapeutic means than it is to the first port and generally is at least about 10 cm from the distal end of the catheter body preferably about 15 cm to about 40 cm.

[0010] In a presently preferred embodiment the catheter is a balloon dilatation catheter adapted to perform PTCA procedures. The catheter has a catheter body with two inner lumen extending essentially the length thereof, one of the lumens being a guidewire-receiving lumen and the other lumen being adapted to direct inflation fluid to the interior of a dilatation balloon on the distal portion of the catheter. One of the attractive features of this catheter design is that the catheter can be used as an over-the-wire type dilatation catheter in a

conventional fashion, yet it allows both the catheter and the guidewire to be exchanged during the PTCA procedure. Similar catheter designs can be used with other intraluminal catheters which have diagnostic or therapeutic means on the distal portion of the catheter.

[0011] To facilitate the separation of the guidewire and the catheter during an exchange thereof, a slit is provided in the wall of the catheter body which defines at least part of the guidewire-receiving inner lumen. The slit extends distally from the first guidewire port, preferably to the second port. A second slit should extend distally from the second guidewire port to a location proximately adjacent the diagnostic or therapeutic means.

[0012] To replace a catheter during an intraluminal procedure such as PTCA, the in-place catheter is pulled proximally over the guidewire from the proximal end of the catheter. If the in-place guidewire extends out the second guidewire port, the catheter is withdrawn peeling the catheter off of the guidewire through the slit extending distally from the second guidewire until the distal end of the catheter exits the proximal end of the guiding catheter or an adapter attached thereto at which point the guidewire can be manually held in position while the catheter is removed from the proximal end thereof. If the in-place guidewire exits the inner lumen of the catheter from the first guidewire port, the catheter is separated from the guidewire by peeling the catheter away from the guidewire through the slit which extends between the first and second guidewire port as the catheter is withdrawn from the proximal end of the guiding catheter or the adapter attached thereto until the guidewire exits the second guidewire port. The separation of the catheter from the guidewire continues as previously described with the catheter being peeled off of the guidewire through the slit which extends distally from the second guidewire port. The catheter is further withdrawn until the distal end of the catheter exits the proximal end of the guiding catheter and which time the guidewire can be manually held while the catheter is pulled off the proximal end of the guidewire.

[0013] Once the catheter has been removed from the proximal end of the in-place guidewire, the proximal end of the in-place guidewire is inserted into the third guidewire port in the distal end of a replacement catheter and then the replacement catheter can be advanced into the patient's vasculature over the in-place guidewire to perform the intravascular procedure. The proximal end of the guidewire can be directed out of either the second or the first guidewire port in the catheter body depending upon the needs of the physician.

[0014] The catheter system of the invention also allows for the exchange of an in-place guidewire during an intraluminal procedure while holding the catheter in place so as to maintain access to the intraluminal position. To replace an in-place guidewire, it is removed from the guidewire-receiving inner lumen of the catheter and the patient by pulling on its proximal end which extends out of the patient. When the in-place guidewire is re-

moved from the inner lumen of the in-place catheter, the replacement guidewire is inserted into the guidewire-receiving inner lumen of the in-place catheter through the proximal guidewire port and advanced through the guidewire-receiving inner lumen and out the third port in the distal end thereof to the desired location within the patient's body lumen. If the in-place guidewire extends out the second guidewire port, it may be desirable to have the replacement guidewire inserted into the proximal portion of the guidewire-receiving inner lumen through the first or proximal guidewire port before the in-place guidewire is removed from the distal portion of the inner lumen so that there is little chance of losing access to the luminal location by the accidental movement of the in-place catheter. When the replacement guidewire is advanced through the in-place catheter and properly positioned in a desired location therein, e.g. across a stenosis in a patient's artery which is to be dilated, the catheter may then be advanced over the replacement guidewire to the desired location so as to perform the desired diagnostic or therapeutic treatment therein.

[0015] The intravascular catheter of the invention also allows for the removal and reinsertion of a guidewire, for example, when the physician wishes to change the shape of the distal end of a guidewire during a procedure. In this operative modality, the in-place guidewire can be withdrawn in essentially the manner described above, the distal tip thereof reshaped and then be re-introduced into the in-place catheter in essentially the same manner as described above.

[0016] As will become more apparent from the following detailed description of the invention, the intravascular catheter system of the invention allows for a wide variety of intravascular procedures which were heretofore impossible to perform with a single catheter system. These and other advantages are described in the following detailed description when taken in conjunction with the accompanying exemplary drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

[0017]

Fig. 1 is an elevational view, partially in section, of a dilatation catheter having a guidewire-receiving inner lumen which embodies some features of the invention.

Fig. 2 is a transverse, cross-sectional view of the catheter shown in Fig. 1 taken along the lines 2-2.

Fig. 3 is a transverse, cross-sectional view of the catheter shown in Fig. 1 taken along the lines 3-3.

Fig. 4 is a transverse, cross-sectional view of the catheter shown in Fig. 1 taken along the lines 4-4.

Fig. 5 illustrates the invention in which a guidewire extends out the proximal end of an adapter mounted on the proximal end of the catheter body.

Fig. 6 is a transverse, cross-sectional view of the catheter shown in Fig. 5 taken along the lines 6-6.

Fig. 7 is a transverse, cross-sectional view of the catheter shown in Fig. 5 taken along the lines 7-7.

DETAILED DESCRIPTION OF THE INVENTION

[0018] Figs. 1-4 illustrate a dilatation catheter 10 embodying some features of the invention which allow for the exchange of a guidewire while the catheter remains in place within the patient and which also allow for the exchange of the catheter while the guidewire remains in place so as to avoid loss of the arterial position. The catheter 10 generally comprises an elongated catheter body 11, an inflation lumen 12 adapted to direct inflation fluid from the proximal end of the catheter body, to the interior of an inflatable balloon 13 on the distal portion of the catheter body and a guidewire-receiving inner lumen 14 extending therein.

[0019] The wall of the catheter body 11 defining at least part of the guidewire-receiving inner lumen 14 has a first guidewire port 15 near the proximal end 16 of the catheter body, a second guidewire port 17 distal to the first port and at least about 10 cm from the distal end of the catheter body and a third guidewire port 18 located in the distal end 18 of the catheter body, wherein the second guidewire port 17 is substantially closer to the third port 18 than the first port 15.

[0020] An adapter 20 is provided on the proximal end 16 of the catheter body 11 to facilitate the introduction of inflation fluid into the inflation lumen 12 which directs the fluid to the interior of the inflatable balloon 13 through the inflation port 22.

[0021] A first slit 23 is preferably provided in the wall of the catheter body which defines the guidewire-receiving inner lumen 14 and extends between the first guidewire port 15 and the second guidewire port 17. A second slit 24 is provided in the wall of the catheter body 11 which further defines the guidewire-receiving inner lumen and extends from the second guidewire port 17 to a location proximal to the proximal end 16 of the balloon 13.

[0022] The catheter body 11 has a tubular extension 26 on the distal portion thereof which extends through the interior and out the distal end of the balloon 13. The tubular extension 26 is adapted to receive a guidewire 27 within the inner lumen 14. The distal end of the guidewire 27 has a coil 28 on the distal end thereof which is shown extending out the third guidewire port 18 in the distal end 19 of the catheter body 11 and has an elongated core member 29 which is shown extending out the second guidewire port 18. The guidewire 27 is shown in phantom in a second position disposed within

the proximal section of the inner lumen 14. The proximal portion of the elongated core member 29 extends out the first guidewire port 15 near the proximal end 16 of the catheter body 11.

[0023] A radiopaque marker 30 is disposed about the tubular extension 26 within the interior of the balloon 13 to facilitate the fluoroscopic observation thereof during an intravascular procedure. Radiopaque markers 31, 32 and 33 may also be provided on the proximal portion of the catheter body 11 to allow the physician to fluoroscopically determine the location of the first and second guidewire ports and the like during the intravascular procedures.

[0024] The catheter system of the invention can be inserted into the patient in a conventional over-the-wire fashion with the guidewire 27 preloaded within the inner lumen 14 and extending proximally out the first or proximal port 15 or it can be inserted in a manner similar to that used to insert catheters having the improvements of Yock and Horzewski *et al.* wherein the guidewire extends proximally out the second or intermediate guidewire port 17. When it becomes desirable or necessary at any time during the intravascular procedure to remove or replace either the catheter 10 or the guidewire 27 either may be removed by pulling on the proximal end thereof which extends out of the patient while the catheter or guidewire which remains within the patient is held in position in order to maintain access to the desired intravascular location.

[0025] If the guidewire is to be removed, the catheter 10 is held in place while the guidewire is pulled out of the proximal end of the guiding catheter and the catheter 10. When the guidewire has been removed from the catheter 10, a replacement guidewire may then be inserted through the first guidewire port 15 which is outside the patient into the inner lumen 14 and advanced therein until the guidewire exits the third guidewire port 18 in the distal end 19 of the catheter body 11 into the patient's coronary artery. Once the replacement guidewire 27 is properly positioned within the patient's artery, *e.g.* across a stenosis to be dilated, the dilatation catheter 10 may then be further advanced within the artery over the replacement guidewire to the desired location therein to perform the dilatation or other diagnostic or therapeutic procedure in a conventional manner.

[0026] If the catheter 10 is to be removed and the guidewire 27 extends proximally out the first guidewire port 15, the guidewire and the catheter are separated while the catheter is being removed by pulling the guidewire through the slit 23 until the guidewire extends out the second guidewire port 17. The peeling of the catheter off of the guidewire 27 continues through the slit 24 while the catheter is being withdrawn. When the distal end 19 of the catheter exits the proximal end of the guiding catheter, the guidewire may be manually gripped and the catheter 10 removed from the proximal end of the guidewire. If the guidewire 27 exits the second guidewire port 17 the procedure is essentially the same

except that there is no need to peel the catheter 10 away from the guidewire through the slit 23 until the guidewire extends through the second guidewire port 17. When the catheter 10 has been removed, the replacement catheter is mounted onto the guidewire 27 by inserting the proximal end of the guidewire through the third guidewire port 18 in the distal end 19 of the replacement catheter and advancing the catheter over the guidewire disposed within the inner lumen 14 of the catheter until the guidewire exits the second guidewire port 17. The replacement catheter may then be inserted into the patient and advanced therein in a conventional manner as described in Yock or Horzewski *et al.* which have been incorporated herein.

[0027] In another method the replacement catheter is mounted onto the guidewire 27 as previously described but the replacement catheter is advanced over the guidewire until the proximal end of the guidewire exits the first guidewire port 15. In this method the replacement catheter is advanced well within the patient's vasculature before the guidewire exits the proximal end of the guidewire exits the first port, it is manually grasped and the replacement catheter advanced further over the wire into the patient's coronary arteries.

[0028] The invention is illustrated in FIGS. 5-7. This embodiment is quite similar to the embodiment shown in FIGS. 1-4 except that the guidewire 27 extends through the center arm of the two arm adaptor 35 on the proximal end of the catheter body 11. The corresponding parts of this embodiment are numbered the same as the parts of the embodiments shown in FIGS. 1-4. The first guidewire port 15 in this embodiment (not shown in the drawings) is in the proximal end 16 of the catheter body 11 and opens to the adaptor 35. The use of this embodiment is the essentially the same as the embodiment shown in FIGS. 1-4. The adaptor 35 is modified to include a slit 44 which is continuous with the slit 23 in the catheter body 11.

[0029] The catheter body 11 can be formed by conventional techniques, *e.g.* extruding, from materials already found useful in intravascular catheters such as polyethylene, polyimide, polyvinyl chloride, polyesters and composite materials such as described in U.S. Patent 4,981,478 (Evard *et al.*). The various components of the catheter can be joined by suitable adhesive such as the acrylonitrile based adhesive sold as Loctite™ 405. Heat shrinking may also be employed where appropriate. A venting means may be provided to remove air from the interior of the balloon before the catheter is inserted into the patient such as described in U.S. Patent 4,638,805 (Powell) and U.S. Patent 4,821,722 (Samson *et al.*).

[0030] The size of the catheter body 11 and the guidewire-receiving inner lumen 14 thereof to a large extent are determined by the size of the guidewires 27 to be employed and the size of the artery or other body lumen through which the catheter must pass. Generally, the diameter of the inner lumen is sufficient to accommodate the guidewire and to allow it to be slidably dis-

posed therein. The diameters of guidewires for coronary use can vary from about 0.008 to about 0.035 inch (0.2-0.89 mm) in diameter, and the inner diameter of the guidewire-receiving inner lumen 14 of the catheter 10 should be about 0.001 to about 0.005 inch (0.025-0.127 mm) larger than the diameter of the guidewire. The catheter body 11 is sufficiently long to extend from outside the proximal end of a guiding catheter, which likewise extends out of the patient, to a stenosis to be treated within the patient's vascular system (or other desired location therein), e.g. from about 100 to about 150 cm when a Seldinger approach through the femoral artery is employed to introduce the catheter 10 into the patient's vasculature. The wall forming the catheter must be of sufficient thickness and strength so that it can be pushed over the guidewire 27 to the desired location within the patient's blood vessel. If desired the proximal portion of the dilatation catheter 10 can be provided with a stiffening means to facilitate the advancement of the catheter within the patient's vasculature.

[0031] While the invention has been described herein in terms of certain presently preferred embodiments directed to balloon dilatation catheters for use in coronary angioplasty procedures, those skilled in the art will recognize that the catheter of the invention may be used in a variety of body lumens. For example, the invention can be utilized in a wide variety of diagnostic and therapeutic intravascular catheters. Additionally, the catheter body may be of concentric construction rather than the dual lumen construction shown herein.

Claims

1. An intravascular catheter system which is adapted for diagnostic or, therapeutic procedures within a patient and which allows the exchange of a guidewire or catheter thereof while the catheter system is disposed within the patient comprising:

- a) an elongated catheter body (11) having proximal (16) and distal (19) ends and a guidewire receiving inner lumen (14) therein extending to the distal end of the catheter body (11);
- b) means (13) mounted on a distal portion of the catheter body for performing a diagnostic or therapeutic procedure;
- c) the guidewire receiving inner lumen extending within the catheter body from the proximal end to the distal end thereof;
- d) a first guidewire port (15) in the distal end of the catheter body which is in fluid communication with the guidewire receiving inner lumen;
- e) a second guidewire port (17) in the catheter body spaced proximal to the distal end of the catheter body;
- f) a slit (23) in the catheter body in communication with the guidewire receiving inner lumen;

characterised by

g) an adapter (35) on the proximal end of the catheter body having

- an inner lumen which extends to and is in fluid communication with the guidewire receiving inner lumen and
- a longitudinally extending slit (44) which is in fluid communication with the inner lumen extending within the adapter and which is in alignment with the slit in the catheter body.

Patentansprüche

1. Gefäßkathetersystem, das sich für Diagnose- oder Behandlungsverfahren in einem Patienten eignet und den Austausch eines Führungsdrahtes oder eines Katheters des Systems ermöglicht, während sich das Kathetersystem im Patienten befindet, wobei das System folgendes umfasst:

- a) einen elongierten Katheterkörper (11) mit proximalen (16) und distalen (19) Enden und einem den Führungsdraht aufnehmenden inneren Lumen (14), das sich zu dem distalen Ende des Katheterkörpers (11) erstreckt;
- b) eine an dem distalen Abschnitt des Katheterkörpers angebrachte Einrichtung (13) zur Ausführung eines Diagnoseoder Behandlungsverfahrens;
- c) wobei sich das den Führungsdraht aufnehmende innere Lumen in dem Katheterkörper von dem proximalen Ende zu dem distalen Ende des Katheterkörpers erstreckt;
- d) eine erste Führungsdrahtöffnung (15) in dem distalen Ende des Katheterkörpers, die sich in Fluidübertragungsverbindung mit dem den Führungsdraht aufnehmenden inneren Lumen befindet;
- e) eine zweite Führungsdrahtöffnung (17) in dem Katheterkörper mit proximalem Abstand zu dem distalen Ende des Katheterkörpers;
- f) einen Schlitz (23) in dem Katheterkörper, der sich in Übertragungsverbindung mit dem den Führungsdraht aufnehmenden inneren Lumen befindet; **gekennzeichnet durch:**
- g) einen Adapter (35) an dem proximalen Ende des Katheterkörpers, der folgendes aufweist:

- ein inneres Lumen, das sich zu dem den Führungsdraht aufnehmenden inneren Lumen erstreckt und sich mit diesem in Fluidübertragungsverbindung befindet; und
- einen sich longitudinal erstreckenden Schlitz (44), der sich in Fluidübertragungsverbindung mit dem den Führungsdraht

aufnehmenden inneren Lumen befindet, das sich in dem Adapter erstreckt und das sich in Ausrichtung mit dem Schlitz in dem Katheterkörper befindet.

Revendications

1. Système de cathéter intravasculaire qui est adapté pour des procédures diagnostiques ou thérapeutiques dans un patient et qui permet le remplacement d'un fil de guidage ou d'un cathéter du système tandis que le système de cathéter est placé dans le patient comprenant :

10

15

a) un corps de cathéter allongé (11) ayant des extrémités proximale (16) et distale (19) et une lumière intérieure (14) recevant un fil de guidage, s'étendant jusqu'à l'extrémité distale du corps de cathéter (11);

20

b) des moyens (13) montés sur une partie distale du corps de cathéter pour réaliser une procédure diagnostique ou thérapeutique ;

c) la lumière intérieure recevant un fil de guidage s'étendant dans le corps de cathéter de son extrémité proximale à son extrémité distale ;

25

d) un premier orifice de fil de guidage (15) dans l'extrémité distale du corps de cathéter qui est en communication par fluide avec la lumière intérieure recevant un fil de guidage ;

30

e) un deuxième orifice de fil de guidage (17) dans le corps de cathéter distant proximale-ment de l'extrémité distale du corps de cathéter ;

f) une fente (23) dans le corps de cathéter en communication avec la lumière intérieure recevant un fil de guidage ; **caractérisé par**

35

g) un adaptateur (35) sur l'extrémité proximale du corps de cathéter ayant

40

une lumière intérieure qui s'étend jusqu'à et qui est en communication par fluide avec la lumière intérieure recevant un fil de guidage et

une fente (44) qui s'étend longitudinalement, qui est en communication par fluide avec la lumière intérieure s'étendant dans l'adaptateur et qui est en alignement avec la fente dans le corps de cathéter.
